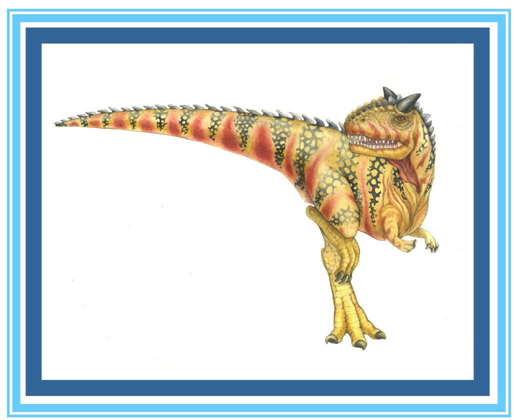
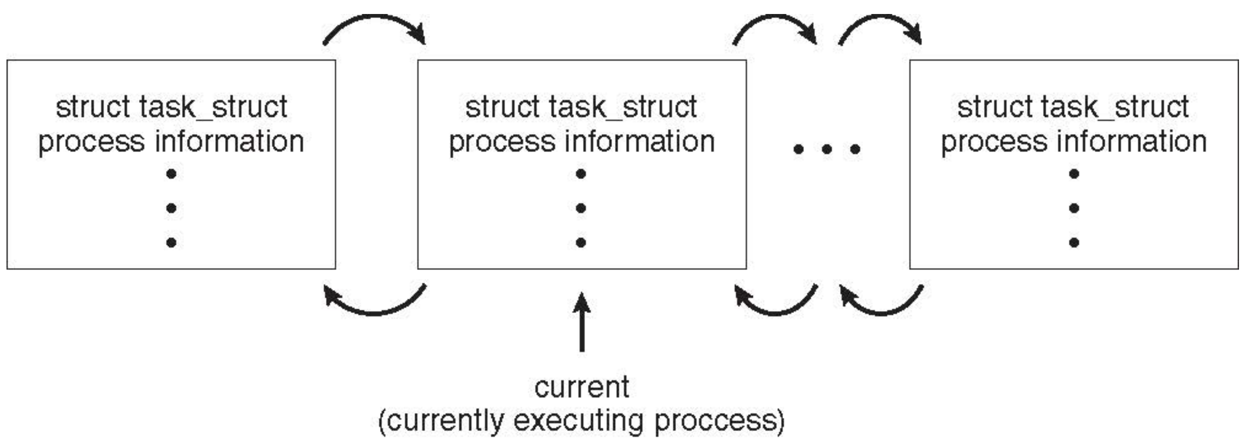
Chapter 3: Processes



Process Representation in Linux

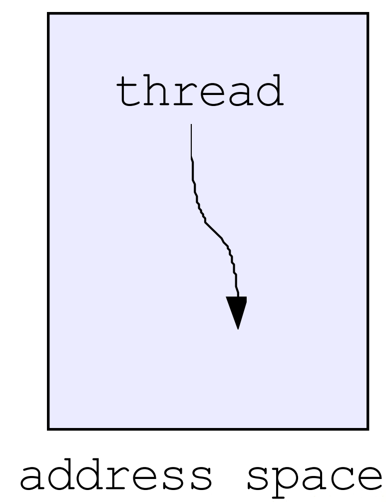
Represented by the C structure `task_struct`

```
pid t_pid; /* process identifier */
long state; /* state of the process */
unsigned int time_slice /* scheduling information */
struct task_struct *parent; /* this process's parent */
struct list_head children; /* this process's children */
struct files_struct *files; /* list of open files */
struct mm_struct *mm; /* address space of this process */
```



What is a “process”?

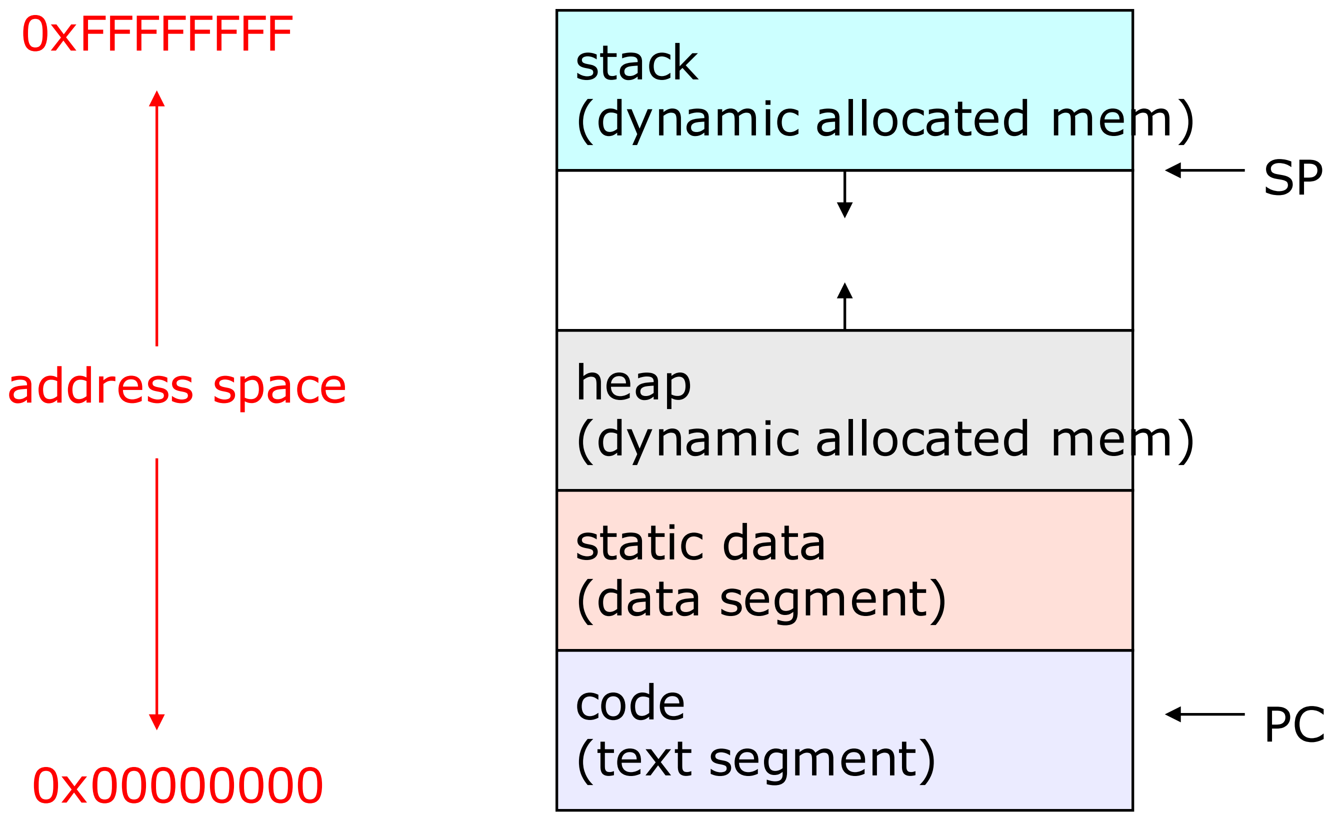
- The process is the OS’s abstraction for execution
  - A process is a program in execution
- Simplest (classic) case: a sequential process
  - An address space (an abstraction of memory)
  - A single thread of execution (an abstraction of the CPU)
- A sequential process is:
  - The unit of execution
  - The unit of scheduling
  - The dynamic (active) execution context
    - vs. the program – static, just a bunch of bytes



What's "in" a process?

- A process consists of (at least):
  - An address space, containing
    - the code (instructions) for the running program
    - the data for the running program (static data, heap data, stack)
  - CPU state, consisting of
    - The program counter (PC), indicating the next instruction
    - The stack pointer
    - Other general purpose register values
  - A set of OS resources
    - open files, network connections, sound channels, …
- In other words, it's all the stuff you need to run the program
  - or to re-start it, if it's interrupted at some point

A process's address space (idealized)

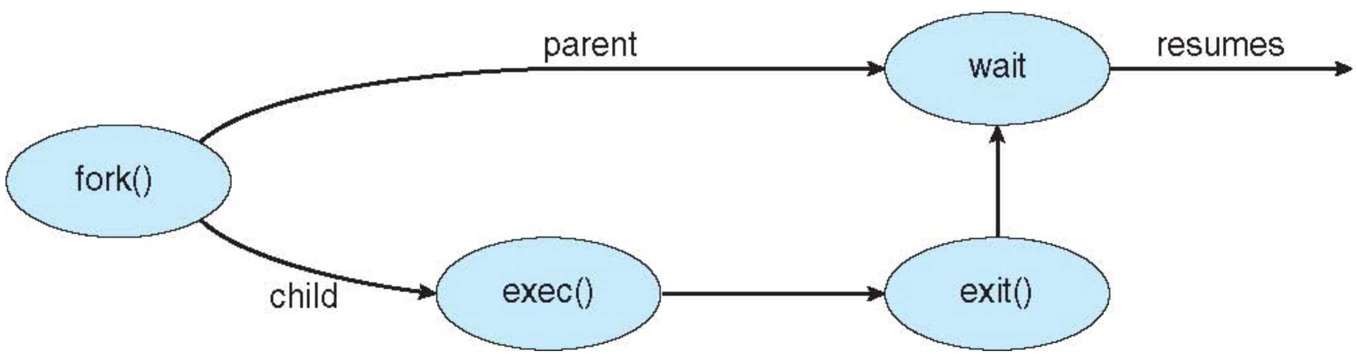


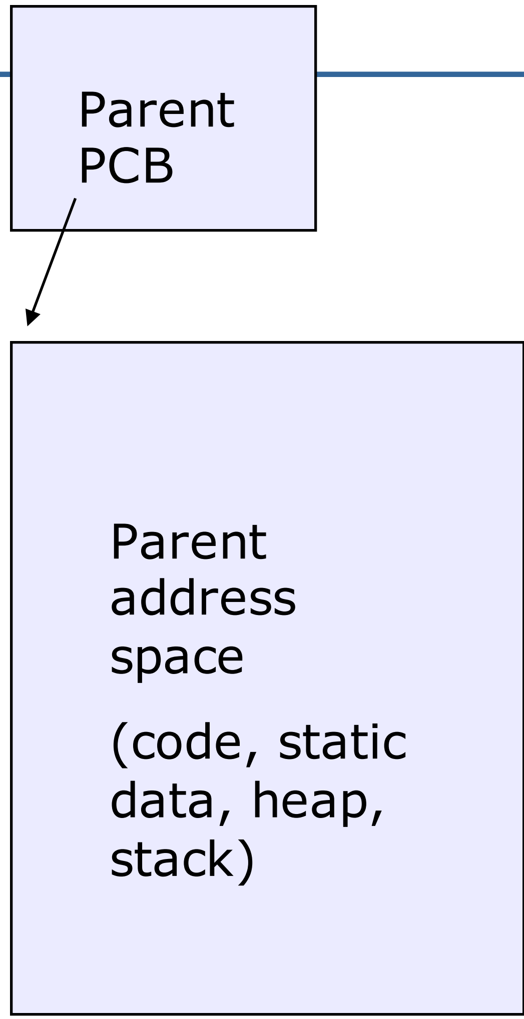
UNIX process creation details

- UNIX process creation through **`fork()`** system call
  - creates and initializes a new PCB
    - initializes kernel resources of new process with resources of parent (e.g., open files)
    - initializes PC, SP to be same as parent
  - creates a new address space
    - initializes new address space with a copy of the entire contents of the address space of the parent
  - places new PCB on the ready queue
- the **`fork()`** system call “returns twice”
  - once into the parent, and once into the child
    - returns the child’s PID to the parent
    - returns 0 to the child
- **`fork()`** = “clone me”

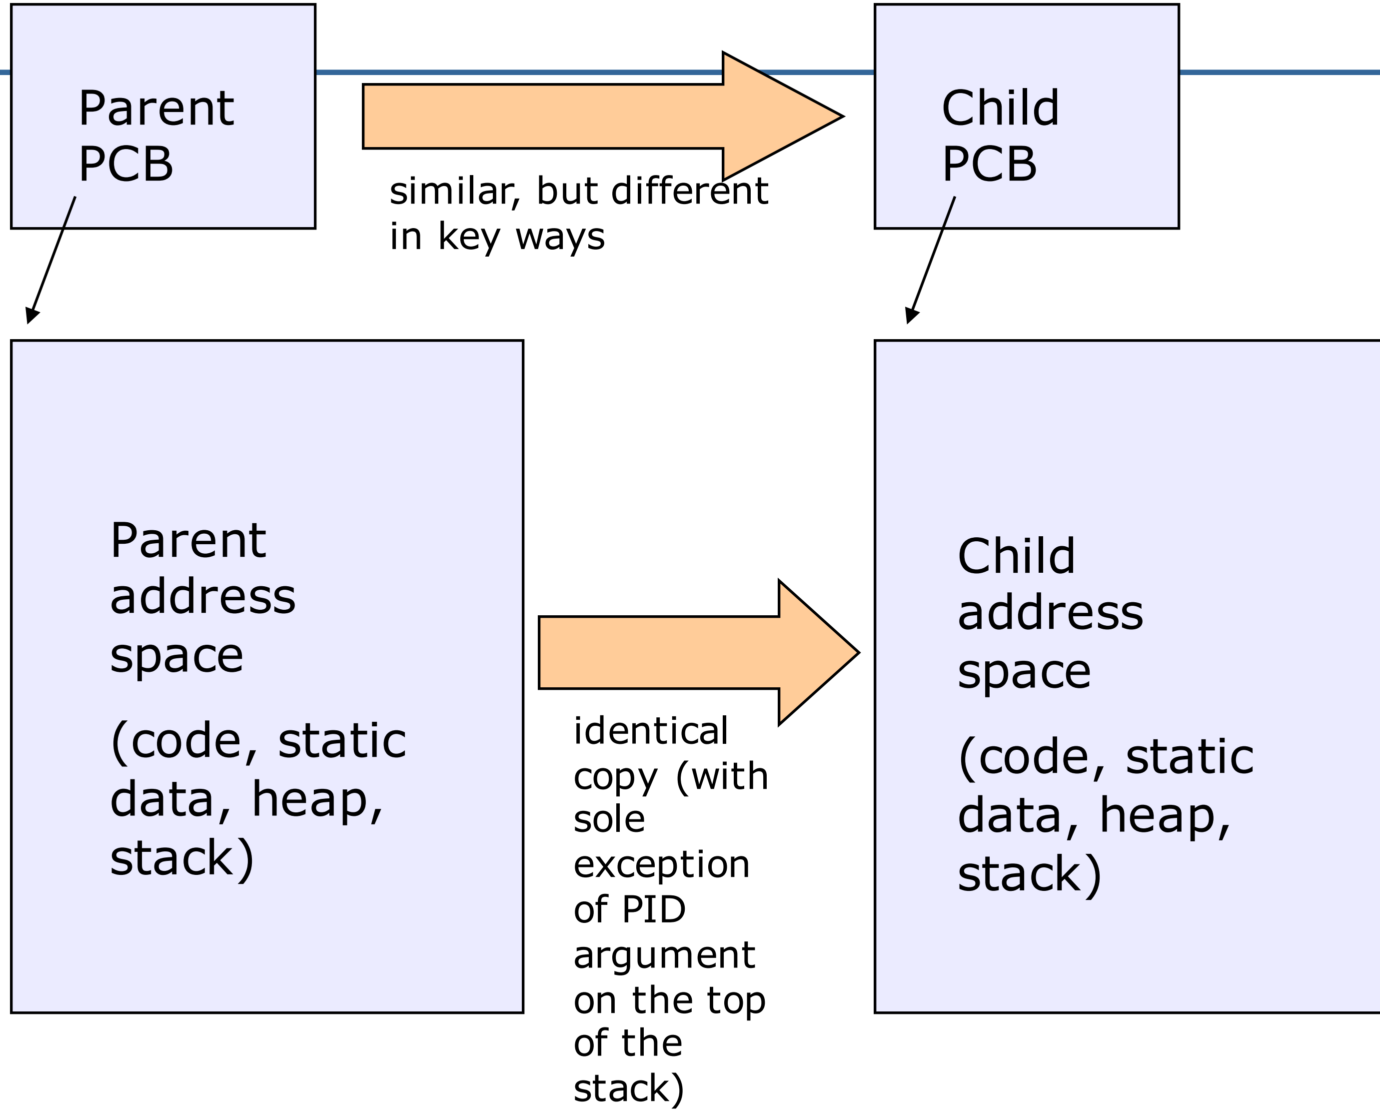
Process Creation (Cont.)

- Address space
  - Child duplicate of parent
  - Child has a program loaded into it
- UNIX examples
  - `fork()` system call creates new process
  - `exec()` system call used after a `fork()` to replace the process' memory space with a **new program**





Parent PCB
Parent address space
(code, static data, heap, stack)



Parent PCB
similar, but different in key ways
Child PCB
Parent address space
(code, static data, heap, stack)
identical copy (with sole exception of PID argument on the top of the stack)
Child address space
(code, static data, heap, stack)

UNIX process creation details

- UNIX process creation through **`fork()`** system call
  - creates and initializes a new PCB
    - initializes kernel resources of new process with resources of parent (e.g., open files)
    - initializes **PC, SP** to be same as parent
  - creates a new address space
    - initializes new address space with a copy of the entire contents of the address space of the parent
  - places new PCB on the ready queue
- the **`fork()`** system call "**returns twice**"
  - once into the parent, and once into the child
    - returns the child's PID to the parent
    - returns 0 to the child
- **`fork()`** is essentially "clone me"

testparent – use of fork( )

```
#include <sys/types.h>
#include <unistd.h>
#include <stdio.h>

int main(int argc, char **argv)
{
  char *name = argv[0];
  int pid = fork();
  if (pid == 0) {
    printf(“Child of %s is %d\n”, name, pid);
    return 0;
  } else {
    printf(“My child is %d\n”, pid);
    return 0;
  }
}
```

exec() vs. fork()

- Q: So how do we start a new program, instead of just forking the old program?
- A: First fork, then exec
  - `int exec(char * prog, char * argv[])`
- **`exec()`**
  - stops the current process
  - loads program ‘prog’ into the address space
    - i.e., over-writes the existing process image
  - initializes hardware context, args for new program
  - places PCB onto ready queue
  - note: *<u>does not create a new process!</u>*

- So, to run a new program:
  - fork()
  - Child process does an exec()
  - Parent either waits for the child to complete, or not

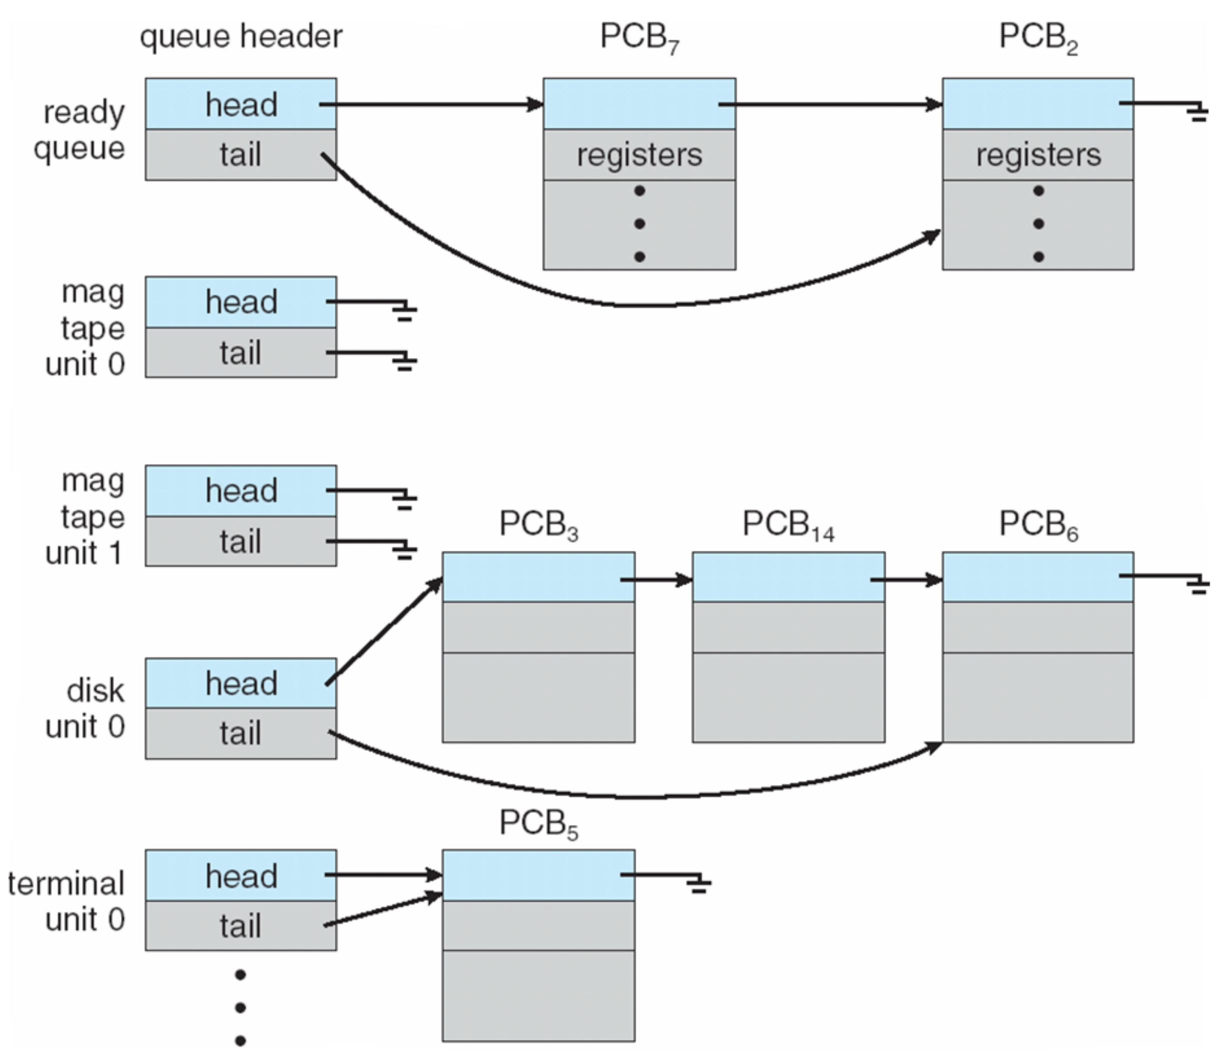
UNIX shells

```
int main(int argc, char **argv)
{
  while (1) {
    printf ("$ ");
    char *cmd = get_next_command();
    int pid = fork();
    if (pid == 0) {
       exec(cmd);
       panic("exec failed!");
    } else {
       wait(pid);
    }
  }
}
```

Process Scheduling

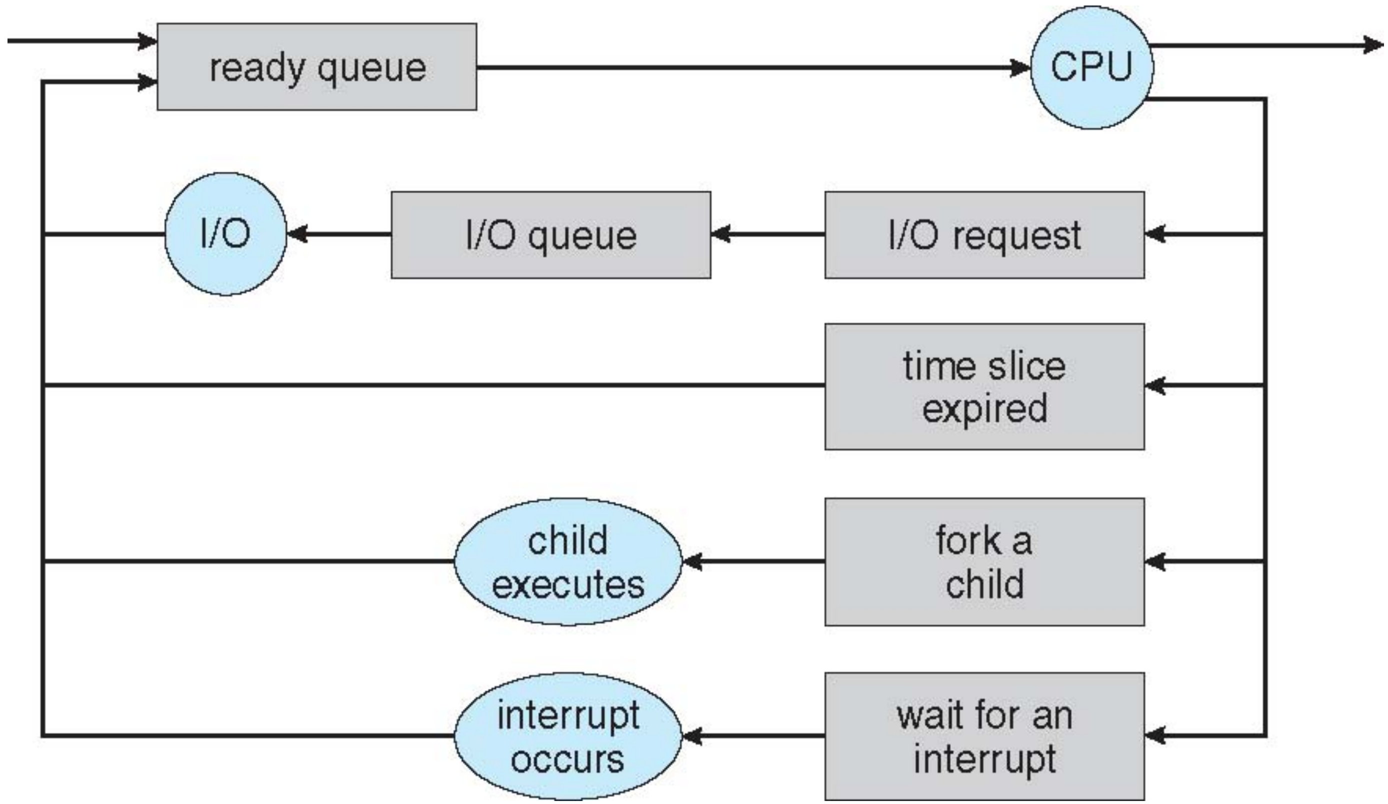
- Maximize CPU use, quickly switch processes onto CPU for time sharing
- **Process scheduler** selects among available processes for next execution on CPU
- Maintains **scheduling queues** of processes
  - **Job queue** – set of all processes in the system
  - **Ready queue** – set of all processes residing in main memory, ready and waiting to execute
  - **Device queues** – set of processes waiting for an I/O device
  - Processes migrate among the various queues

Ready Queue And Various I/O Device Queues



Representation of Process Scheduling

- **Queueing diagram** represents queues, resources, flows (sorta!?)



Context Switch

- When CPU switches to another process, the system must **save the state** of the old process and load the **saved state** for the new process via a **context switch**
- **Context** of a process represented in the PCB
- Context-switch time is overhead; the system does no useful work while switching
  - The more complex the OS and the PCB ➔ the longer the context switch
- Time dependent on hardware support
  - Some hardware provides multiple sets of registers per CPU ➔ multiple contexts loaded at once

Operations on Processes

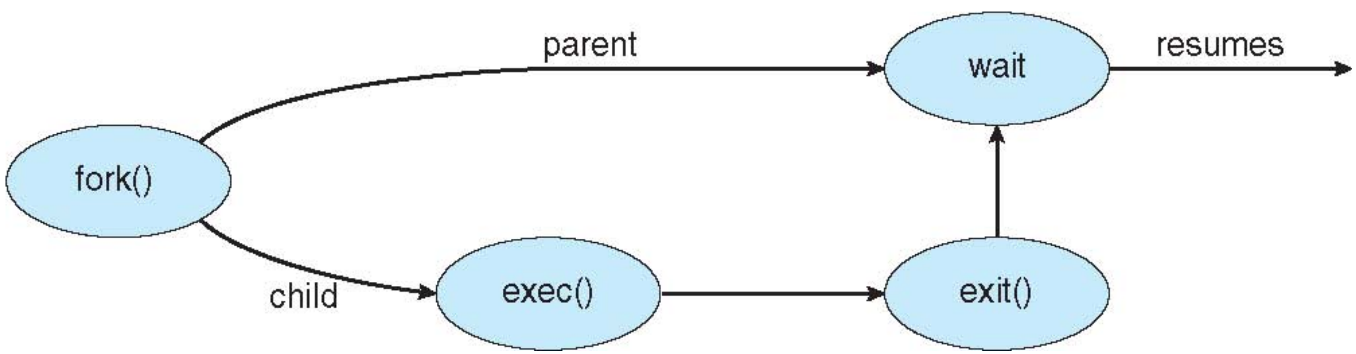
- System must provide mechanisms for:
  - process creation,
  - process termination,
  - and so on as detailed next

Process Creation

- **Parent** process create **children** processes, which, in turn create other processes, forming a **tree** of processes
- Generally, process identified and managed via a **process identifier** (**pid**)
- Resource sharing options
  - Parent and children share all resources
  - Children share subset of parent's resources
  - Parent and child share no resources
- Execution options
  - Parent and children execute concurrently
  - Parent waits until children terminate

Process Creation (Cont.)

- Address space
  - Child duplicate of parent
  - Child has a program loaded into it
- UNIX examples
  - **`fork()`** system call creates new process
  - **`exec()`** system call used after a **`fork()`** to replace the process' memory space with a **new program**



C Program Forking Separate Process

```
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

int main()
{
pid_t pid;

   /* fork a child process */
   pid = fork();

   if (pid < 0) { /* error occurred */
      fprintf(stderr, "Fork Failed");
      return 1;
   }
   else if (pid == 0) { /* child process */
      execlp("/bin/ls","ls",NULL);
   }
   else { /* parent process */
      /* parent will wait for the child to complete */
      wait(NULL);
      printf("Child Complete");
   }

   return 0;
}
```

Process Termination

- Process executes last statement and then asks the operating system to delete it using the `exit()` system call.
  - Returns status data from child to parent (via `wait()`)
  - Process' resources are deallocated by operating system
- Parent may terminate the execution of children processes using the `abort()` system call. Some reasons for doing so:
  - Child has exceeded allocated resources
  - Task assigned to child is no longer required
  - The parent is exiting and the operating systems does not allow a child to continue if its parent terminates

Process Termination

- Some operating systems do not allow child to exist if its parent has terminated.
  - If a process terminates, then all its children must also be terminated.
  - **cascading termination.** All children, grandchildren, etc. are terminated.
  - The termination is initiated by the operating system.
- The parent process may wait for termination of a child process by using the **`wait()`** system call. The call returns status information and the pid of the terminated process

```
pid = wait(&status);
```

- If no parent waiting (did not invoke **`wait()`**) process is a **zombie**
- If parent terminated without invoking **`wait`**, process is an **orphan**
